

Features

- Three-phase gate drivers
 - High voltage rail up to 250 V
 - Driver current capability:
 - STSPIN32F0251: 200/350 mA source/sink current
 - STSPIN32F0252: 1/0.85 A source/sink current
 - dV/dt transient immunity ± 50 V/ns
 - Gate driving voltage range from 9V to 20V
- 32-bit ARM[®] Cortex[®]-M0 core:
 - Up to 48 MHz clock frequency
 - 4-Kbyte SRAM with HW parity
 - 32-Kbyte Flash memory with option bytes used for write/readout protection
- 21 general-purpose I/O ports (GPIO)
- 6 general-purpose timers
- 12-bit ADC converter (up to 10 channels)
- I²C, USART and SPI interfaces
- Matched propagation delay for all channels
- Integrated bootstrap diodes
- Comparator for fast over current protection
- UVLO, Interlocking and deadtime functions
- Smart shutdown (smartSD) function
- Standby mode for low power consumption
- On-chip debug support via SWD
- Extended temperature range: -40 to +125 °C

Applications

- Battery operated and 110 Vac supplied power and garden tools
- Industrial fans and pumps
- Home appliances
- Industrial and home automation

Description

The STSPIN32F025x system-in-package is an extremely integrated solution for driving three-phase applications, helping designers to reduce PCB area and overall bill-of-material.

It embeds an STM32F031x6x7 featuring an ARM[®] 32-bit Cortex[®]-M0 CPU and a 250 V triple half-bridge gate driver, able to drive N-channel power MOSFETs or IGBTs.

A comparator featuring advanced smartSD function is integrated, ensuring fast and effective protection against overload and overcurrent.

The high-voltage bootstrap diodes are also integrated, as well as anti cross-conduction, deadtime and UVLO protection on both the lower and upper driving sections, which prevents the power switches from operating in low efficiency or dangerous conditions. Matched delays between low and high-side sections guarantee no cycle distortion.

The integrated MCU allows performing FOC, 6-step sensorless and other advanced driving algorithms including the speed control loop.

Table 1. Legend/abbreviations used in the pin description table

Name	Abbreviation	Definition
Pin name	Unless otherwise specified in brackets below the pin name, the pin function during and after reset is the same as the actual pin name	
Pin type	AO	Gate Driver Analog Output
	P	Gate Driver Supply \ GND pin
	S	Supply pin
	I	Input-only pin
	I/O	Input / output pin
I/O structure	FT	5 V-tolerant I/O
	FTf	5 V-tolerant I/O, FM+ capable
	TTa	3.3 V-tolerant I/O directly connected to ADC
	TC	Standard 3.3V I/O
	B	Dedicated BOOT0 pin
	RST	Bidirectional reset pin with embedded weak pull-up resistor
Notes	Unless otherwise specified by a note, all I/Os are set as floating inputs during and after reset	
Pin functions	Alternate functions	Functions selected through GPIOx_AFR registers
	Additional functions	Functions directly selected/enabled through peripheral registers

Table 2. Pin description

N.	Name	Type	Function
1	PB8	I/O - FTf	MCU PB8
2	VSS	Supply	MCU digital ground

1. The circuit guarantees less than 1 V on the LVG and HVG pins (at $I_{sink} = 10 \text{ mA}$), with $VCC > 3 \text{ V}$. This allows omitting the “bleeder” resistor connected between the gate and the source of the external MOSFETs normally used to hold the pin low. When the EN is set low, gate driver outputs are forced low and assure low impedance.

Table 3. STSPIN32F025x MCU-Driver internal connections

MCU pad	Type	Controller pad	Function
PB12	I/O - FT	$\overline{\text{FAULT}}$	Gate Driver Fault output
PB13	I/O - FT	$\overline{\text{LIN1}}$	Gate Driver Low-Side input driver 1

5 Device description

The STSPIN32F025x is a system-in-package providing an integrated solution suitable for driving high-voltage 3-phase applications.

5.1 Gate driver

The STSPIN32F025x integrates a triple half-bridge gate driver able to drive N-channel power MOSFETs or IGBTs. The high-side section is supplied by a bootstrapped voltage technique with integrated bootstrap diode.

All the inputs lines are connected to a pull-down resistor with typical value of 60 k Ω .

The high- and low-side outputs of same half-bridge cannot be simultaneously driven high thanks to an integrated interlocking function.

5.1.1 Inputs and outputs

The device is controlled through the following logic inputs:

- EN: enable input, active high;
- LIN: low-side driver inputs, active low;
- HIN: high-side driver inputs, active low.

Table 8. Inputs truth table (applicable when device is not in UVLO or SmartSD protection)

	Input pins			Output pins	
	EN	$\overline{\text{LIN}}$	$\overline{\text{HIN}}$	LVG	HVG
	L	X	X	Low	Low
	H	H	H	Low	Low
	H	L	H	HIGH	Low
	H	H	L	Low	HIGH
Interlocking	H	L	L	Low	Low

1. X: don't care

The FAULT and OD pins are open-drain outputs. The FAULT signal is set low in case VCC UVLO is detected, or in case the SmartShutDown comparator triggers an event. It is only used to signal a UVLO or SmartSD activation to external circuits, and its state does not affect the behavior of other functions or circuits inside the driver. The OD behavior is explained in [Section 5.1.5](#).

5.1.2 Deadtime

The deadtime feature, in companion with the interlocking feature, guarantees that driver outputs of the same channel are not high simultaneously and at least a DT time passes between the turn-off of one driver's output and the turn-on of the companion output of the same channel. If a deadtime longer than the internal DT is applied to LIN and HIN inputs by

the external controller, the internal DT is ignored and the outputs follow the deadtime determined by the inputs. Refer to [Figure 4](#) for the deadtime and interlocking waveforms.

5.1.3 VCC UVLO protection

Undervoltage protection is available on VCC and BOOT supply pins. In order to avoid intermittent operation, a hysteresis sets the turn-off threshold with respect to the turn-on threshold.

When VCC voltage goes below the $V_{CCthOFF}$ threshold all the outputs are switched off, both LVG and HVG. When VCC voltage reaches the V_{CCthON} threshold the driver returns to normal operation and sets the LVG outputs according to actual input pins status; HVG is also set according to input pin status if the corresponding V_{BO} section is not in UVLO condition. The FAULT output is kept low when VCC is in UVLO condition. The following figures show some examples of typical operation conditions.

Figure 6. VCC power ON and UVLO, LVG timing

Figure 7. VCC power ON and UVLO, HVG timing

5.1.4 V_{BO} UVLO protection

Dedicated undervoltage protection is available on each bootstrap section between $BOOTx$ and $OUTx$ supply pins. In order to avoid intermittent operation, a hysteresis sets the turn-off threshold with respect to the turn-on threshold.

When V_{BO} voltage goes below the $V_{BOthOFF}$ threshold, the HVG output of the corresponding bootstrap section is switched off. When V_{BO} voltage reaches the V_{BOthON} threshold the device returns to normal operation and the output remains off up to the next input pins transition that requests HVG to turn on.

Figure 8. V_{BO} Power-ON and UVLO timing

5.1.5 Comparator and Smart shutdown

The STSPIN32F025x integrates a comparator committed to the fault protection function, thanks to the SmartShutDown (SmartSD) circuit.

The SmartSD architecture allows immediate turn-off of the gate driver outputs in the case of overload or overcurrent condition, by minimizing the propagation delay between the fault detection event and the actual output switch-off. In fact, the time delay between the fault detection and the output turn-off is not dependent on the value of the external components connected to the OD pin, which are only used to set the duration of disable time after the fault.

This provides the possibility to increase the duration of the output disable time after the fault event up to very large values without increasing the delay time of the protection. The duration of the disable time is determined by the values of the external capacitor C_{OD} and of the optional pull-up resistor connected to the OD pin.

The comparator has an internal voltage reference V_{REF} connected to the inverting input, while the non-inverting input is available on the CIN pin. The comparator's CIN input can be connected to an external shunt resistor in order to implement a fast and simple overcurrent protection function. The output signal of the comparator is filtered from glitches shorter than t_{FCIN} and then fed to the SmartSD logic.

If the impulse on the CIN pin is higher than V_{REF} and wider than t_{FCIN} , the SmartSD logic is triggered and immediately sets all of the driver outputs to low-level (OFF).

At the same time, FAULT is forced low to signal the event (for example to a MCU input) and OD starts to discharge the external C_{OD} capacitor used to set the duration of the *output disable time* of the fault event.

The FAULT pin is released and driver outputs restart following the input pins as soon as the *output disable time* expires.

The overall disable time is composed of two phases:

- The OD *unlatch time* (t_1 in [Figure 9](#)), which is the time required to discharge the C_{OD} capacitor down to the V_{SSDI} threshold. The discharge starts as soon as the SSD comparator is triggered.
- The OD *Restart time* (t_2 in [Figure 9](#)), which is the time required to recharge the C_{OD} capacitor up to the V_{SSDh} threshold. The recharge of C_{OD} starts when the OD internal MOSFET is turned-off, which happens when the fault condition has been removed ($CIN < V_{REF} - C_{INhyst}$) and the voltage on OD reaches the V_{SSDI} threshold. This time normally covers most of the overall output disable time.

If no external pull-up is connected to OD, the external C_{OD} capacitor is discharged with a time constant defined by C_{OD} and the internal MOSFET's characteristic ([Equation 1](#)), and the *Restart time* is determined by the internal current source I_{OD} and by C_{OD} ([Equation 2](#)).

Equation 1

$$t_1 \cong R_{ON_OD} \cdot C_{OD} \cdot \ln \left(\frac{V_{OD}}{V_{SSDI}} \right)$$

Equation 2

$$t_2 \cong \frac{C_{OD} \cdot V_{SSDh}}{I_{OD}} \cdot \ln \left(\frac{V_{SSDI} - V_{OD}}{V_{SSDh} - V_{OD}} \right)$$

Where $V_{OD} = V_{FLOAT_OD}$

In case the OD pin is connected to VCC by an external pull-up resistor R_{OD_ext} , the OD discharge time is determined by the external network R_{OD_ext} C_{OD} and by the internal MOSFET's R_{ON_OD} ([Equation 3](#)), while the *Restart time* is determined by current in R_{OD_ext} ([Equation 4](#)).

Equation 3

$$t_1 \cong C_{OD} \cdot (R_{OD_ext} // R_{ON_OD}) \cdot \ln \left(\frac{V_{OD} - V_{on}}{V_{SSDI} - V_{on}} \right)$$

Equation 4

$$t_2 \cong C_{OD} \cdot R_{OD_ext} \cdot \ln \left(\frac{V_{SSDI} - V_{OD}}{V_{SSDh} - V_{OD}} \right)$$

where

$$V_{on} = \frac{R_{ON_OD}}{R_{OD_ext} + R_{ON_OD}} \cdot VCC; \quad V_{OD} = VCC$$

Figure 9. Smart shutdown timing waveforms

5.2 Microcontroller unit

The integrated MCU is the STM32F031x6 with the following main characteristics:

- Core: ARM® 32-bit Cortex® -M0 CPU, frequency up to 48 MHz
- Memories: 4kB of SRAM, 32 kB of Flash Memory
- CRC calculation unit
- Up to 21 fast I/Os
- Advanced-control timer dedicated for PWM generation
- Up to 6 general purpose timers
- 12-bit ADC (up to 10 channels)

- Communication interfaces: I²C, USART, SPI
- Serial Wire Debug (SWD)
- Extended temperature range: -40 to 125°C

Note: For more details refer to the STM32F031x6 datasheet on www.st.com.

5.2.1 Memories and boot mode

The device has the following features:

- 4 Kbytes of embedded SRAM accessed (read/write) at CPU clock speed with 0 wait states and featuring embedded parity checking with exception generation for fail-critical applications.
- The non-volatile memory is divided into two arrays:
 - 32 Kbytes of embedded Flash memory for programs and data
 - Option bytes

The option bytes are used to write-protect the memory (with 4 KB granularity) and/or readout-protect the whole memory with the following options:

- Level 0: no readout protection
- Level 1: memory readout protection, the Flash memory cannot be read from or written to if either debug features are connected or boot in RAM is selected
- Level 2: chip readout protection, debug features (Cortex®-M0 serial wire) and boot in RAM selection disabled.

At startup, the boot pin and boot selector option bit are used to select one of the three boot options:

- boot from User Flash memory
- boot from System Memory
- boot from embedded SRAM

The boot loader is located in System Memory, programmed by ST during production. It is used to reprogram the Flash memory by using USART on pins PA14/PA15.

5.2.2 Power management

The VDD pin is the power supply for I/Os and the internal regulator.

The VDDA pin is power supply for ADC, Reset blocks, RCs and PLL. The VDDA voltage is provided externally through VDDA pin.

Note: The VDDA voltage level must be always greater or equal to the VDD voltage level and must be established first.

The MCU has integrated power-on reset (POR) and power-down reset (PDR) circuits. They are always active, and ensure proper operation above a threshold of 2 V. The device remains in reset mode when the monitored supply voltage is below a specified threshold, $V_{POR/PDR}$, without the need for an external reset circuit.

- The POR monitors only the VDD supply voltage. During the startup phase it is required that VDDA should arrive first and be greater than or equal to VDD.
- The PDR monitors both the VDD and VDDA supply voltages, however the VDDA power supply supervisor can be disabled (by programming a dedicated Option bit) to reduce the

power consumption if the application design ensures that VDDA is higher than or equal to VDD.

The device features an embedded programmable voltage detector (PVD) that monitors the VDD power supply and compares it to the VPVD threshold. An interrupt can be generated when VDD drops below the VPVD threshold and/or when VDD is higher than the VPVD threshold. The interrupt service routine can then generate a warning message and/or put the MCU into a safe state. The PVD is enabled by software.

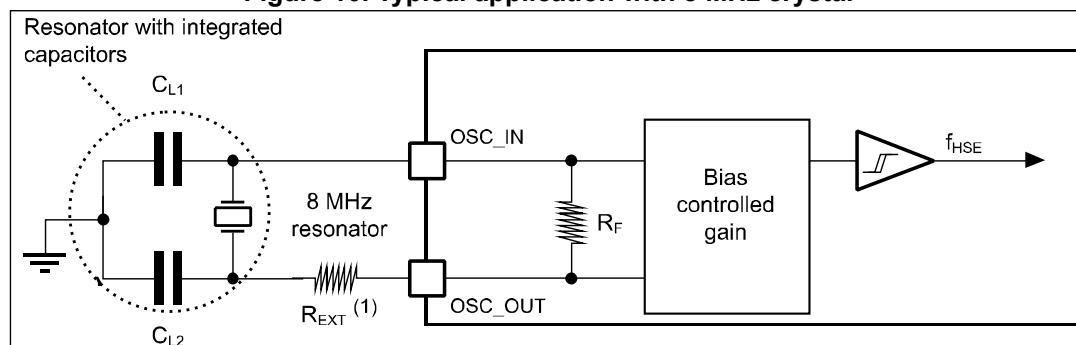

The MCU supports three low-power modes to achieve the best compromise between low power consumption, short startup time and available wakeup sources:

- **Sleep mode**
In Sleep mode, only the CPU is stopped. All peripherals continue to operate and can wake up the CPU when an interrupt/event occurs.
- **Stop mode**
Stop mode achieves very low power consumption while retaining the content of SRAM and registers. All clocks in the 1.8 V domain are stopped, the PLL, the HSI RC and the HSE crystal oscillators are disabled. The voltage regulator can also be put either in normal or in low power mode.
The device can be woken up from Stop mode by any of the EXTI lines (one of the 16 external lines, the PVD output, RTC, I²C1 or USART1).
- **Standby mode**
The Standby mode is used to achieve the lowest power consumption. The internal voltage regulator is switched off so that the entire 1.8 V domain is powered off. The PLL, the HSI RC and the HSE crystal oscillators are also switched off. After entering Standby mode, SRAM and register contents are lost except for registers in the RTC domain and Standby circuitry.
The device exits Standby mode when an external reset (NRST pin), an IWDG reset, a rising edge on the WKUP pins, or an RTC event occurs.

5.2.3 High-speed external clock source

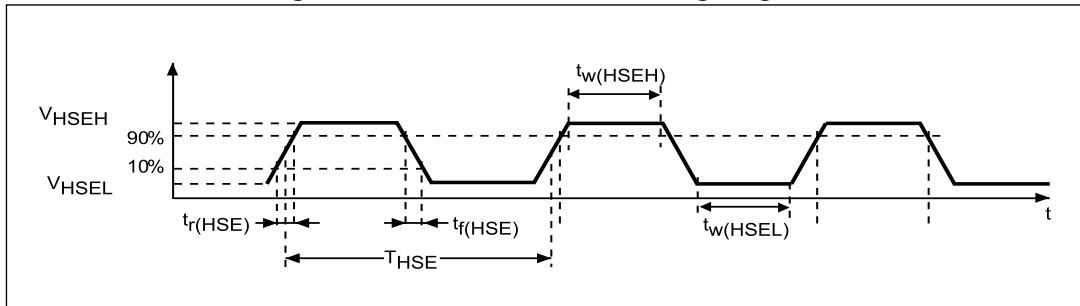

The high-speed external (HSE) clock can be generated from external clock signal or supplied with a 4 to 32 MHz crystal/ceramic resonator oscillator (see [Figure 10](#)). In the application, the resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time.

Figure 10. Typical application with 8 MHz crystal

1. The R_{EXT} value depends on the crystal characteristics (refer to the crystal resonator manufacturer for more details on them).
2. The external clock signal has to respect the I/O characteristics and follows recommended clock input waveform (refer to [Figure 11](#)).

Figure 11. HSE clock source timing diagram

5.3 Advanced-control timer (TIM1)

The advanced-control timer (TIM1) can be seen as a three-phase PWM multiplexed on six channels. It has complementary PWM outputs with programmable inserted deadtimes.

This timer is used to generate the PWM signal for the three half-bridge gate drivers as shown in [Table 9](#).

Table 9. TIM1 channel configuration

MCU I/O	ASIC input	TIM1 channel
PB13	LIN1	TIM1_CH1N
PB14	LIN2	TIM1_CH2N
PB15	LIN3	TIM1_CH3N
PA8	HIN1	TIM1_CH1
PA9	HIN2	TIM1_CH2
PA10	HIN3	TIM1_CH3

6 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK[®] packages, depending on their level of environmental compliance. ECOPACK[®] specifications, grade definitions and product status are available at: www.st.com. ECOPACK[®] is an ST trademark.
